

Dimuon bump cross check

Reminder

- ▶ Sasha showed a 5-6 sigma bump in the dimuon mass distribution last week
- ▶ Much effort is being put into cross-checking it in the higgs-exo group
- ▶ We have the full single mu primary dataset processed for our trigger efficiency studies

Ntuples

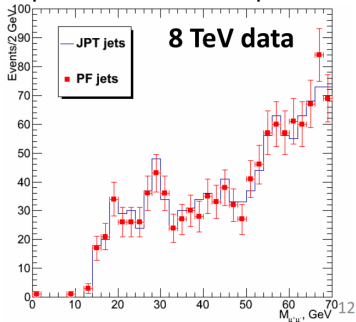

- ▶ Use common ntuple format of $H \rightarrow \tau\tau/inv$.
- ▶ Ntuples have no skimming so all events present
- ▶ Make Light trees requiring events pass data quality cuts and have two muons with $M_{\mu\mu} < 70$ GeV and a CSVL b jet
- ▶ All my plots are of dimuon mass in GeV

- ▶ Require: 2 μ with $p_T > 25$ GeV + jet 1 central and with CSV>0.783
- ▶ Right hand plot also has extra jet veto
- ▶ Both show 2-3 sigma bump

My Plot

September 1st 2014 plot

Same binning

- ▶ Previous slide binning was slightly different to September 1st
- ▶ Change to same 2 GeV bins:
 - Left bins starting at 0, right starting at 1
- ▶ Significance very sensitive to minor details

Adding cuts - additional central jet veto

- Start adding the other cuts present in Sasha et al analysis
 - First go from requiring jet 1 central and with $CSV > 0.783$ to requiring that there is one and only one central jet and it has $CSV > 0.783$

Adding cuts - b tag threshold

- ▶ Next noticed that 0.783 is medium WP for CSVV1 not CSV
- Change threshold to CSVM threshold=0.679

Adding cuts - forward jet

- ▶ Add requirement of at least one forward jet $p_T > 30$ GeV
- ▶ Almost all events removed
- ▶ Could point to forward jet ID difference

Caveats

- ▶ All prepared very quickly
- ▶ Small number of files had xrootd issue when reading
 - Shouldn't cause big effect unless all of bump is in a few runs coincidentally missed

Summary

- ▶ ~ 3 sigma bump seen last year appears to be present in my ntuples too
- ▶ Moving cuts towards Sasha et als appears to reduce the bump
- ▶ Further investigation with Sasha needed
